SHORT · PYSPARK GROUPBY

groupBy aggregations in PySpark

groupBy splits rows into buckets. Aggregations like count and sum summarize each bucket, turning many order rows into a revenue report.

Key points

- Actual Free Edition: six valid orders totaling 142.50.
- Five region/category buckets: EAST/Books 12, NORTH/Books 20, NORTH/Toys 60, SOUTH/Toys 25, WEST/Books 25.50.
- Region rollup: NORTH led at 80.00.
- Windows can rank rows and compute a running total on top of that.

Tiny example

Validated Part 2 aggregation. Numbers are actual Free Edition results.

```
summary = (valid
  .groupBy("region","category")
  .agg(F.count("*").alias("orders"),
       F.sum("order_total").alias("revenue"))
  .orderBy("region","category"))
# Actual: 5 buckets / 6 orders / 142.50
```

Misconception check

> groupBy alone does not print totals. You need aggregations (count, sum, avg) after the group. An unpartitioned window can warn about moving all data to one partition.

Remember

groupBy builds the buckets, and aggregations fill them in.

Validated on Databricks Free Edition with serverless compute and Unity Catalog. No paid features are needed for this Short.
